

External-Constraint Test (SCALULAR-classified) — Audit Ledger v1.0

Test (canon form): A boundary, symmetry, or equivalence claim PASSES only if it constrains a *family* of objects via a structural property *external to* the claim's own definition. If the claim is recovered just by unpacking the definition of the quantity it's about, it FAILS — it's a restatement wearing a name, not a finding.

Scope of this pass: every claim explicitly flagged, proposed, or tested across this session and the directly-linked prior sessions. Not an exhaustive sweep of the full ~2,078-instrument archive — flag if you want a deeper pass against a named instrument set.

PASS

Claim	External structural property invoked
VEILED-Z	Petermann factor divergence — derived from non-orthogonal mode coupling, not asserted
Funnel / branch-point cone geometry	Universal cone geometry near a branch point — independent geometric fact
Conditioned-RESPONSE_ZONE	Behavioral gate design grounded in stated mechanism, not label-matching
Normality Exclusion Boundary (N(Z) Foreclosure Condition)	$SO(2)$ abelian closure — holds for the entire rotation family, proven independent of $\Delta(J)$'s definition
CORDIC trajectory $\leftrightarrow$ eigenvector conjugate pair (Reading B)	Same conjugate symmetry $e^{\pm i\theta}$ appears at iteration level and operator level — derived, not assigned

FAIL — with repair action

Claim	Why it fails	Repair
JAS×EMA=72 $\equiv$ 36×2 (DOB chain)	Both independently constructed to hit 72; no external property forces them to be the <i>same</i> 72	Retain 72 as a fixed canonical anchor (already locked). Remove " $\equiv$ " / convergence framing. State plainly: two independent constructions reaching the same target value — not evidence of a shared mechanism.
$\varphi \equiv$ EP branch exponent	Different universality classes (established prior session)	Keep φ and the EP branch exponent as separate, unequated constructs.
$V(\psi) \equiv$ JAS(EMA)	Static object equated to dynamic object	Do not equate. Retain both, separately defined.
"Defectiveness Exclusion Boundary" (EP-side mirror of Normality Exclusion Boundary)	Tautological — $\Delta(J) > 0$ is the definition of non-normal; nothing external is constrained	Do not name. Refer to descriptively only ("non-normal by definition at the EP"), no boundary-name treatment.
N(Z) / ZEUS as Yin-Yang, Reading A (the dial's two poles)	No mutual containment, no cyclical return — a static bounded interval, not Yin-Yang	Retain N(Z) as a bounded index. Drop Yin-Yang framing for the dial itself; reserve it for Reading B only.

FLAGGED — not failed, held to lower evidentiary status

Claim	Status
ZEUS "Zipper" term	Interpretive label for a real, derived mechanism (eigenvector convergence) — acceptable as naming, not citable as independent proof of that mechanism.
"United Spectrum" naming asymmetry	Names the $N = -1$ pole exactly (eigenvalue coalescence, derived); does not separately name $N = +1$. Property of the <i>label</i> , not a defect in the index. No repair needed — flagged for awareness only.

Net read: the test cleanly separates two classes that look superficially similar in this corpus — derivations using an external structural fact (group closure, divergence behavior, geometric universality) vs. constructions where two independently-chosen numbers or labels are pointed at each other and called convergence. Five pass, four fail, two flagged. The fails cluster on one signature every time: numerology/labeling without an external constraint doing the work.

Recursive Validity Check (self-application)

The test can be applied to itself, using the deduction/induction cross rather than self-assertion:

Arm	Path	Content
Deduction	Theory → Prediction	Theory = the analytic/synthetic distinction (standard, ERES-external epistemology). Prediction = the test's specific rule ("must constrain via an external structural property").
Induction	Data → Inference	Data = the nine audited cases above, sorted independently. Inference = the pattern recovered from them: fails share an independently-constructed-numbers/labels signature; passes share a derivation-from-external-invariant signature.

Result: the two arms converge on the same rule from independent directions — the test passes itself.

Standing condition for any future recursive pass: this only holds because the *Theory* node sits outside the ERES corpus (general epistemology, not an ERES-internal claim). If a future self-check used an ERES-internal claim as the Theory node, the check would fail by its own rule — two internally-constructed things validating each other is exactly the JAS×EMA=72≡36×2 failure mode, one level up. Any recursive application must re-verify this condition before counting as a pass.
